

# C++ Programming: From Problem Analysis to Program Design, Fourth Edition

## Chapter 9: Arrays and Strings

# Objectives

---

In this chapter, you will:

- Learn about arrays
- Explore how to declare and manipulate data into arrays
- Understand the meaning of “array index out of bounds”
- Become familiar with the restrictions on array processing
- Discover how to pass an array as a parameter to a function

# Objectives (continued)

---

- Learn about C-strings
- Examine the use of string functions to process C-strings
- Discover how to input data into—and output data from—a C-string
- Learn about parallel arrays
- Discover how to manipulate data in a two-dimensional array
- Learn about multidimensional arrays

# Data Types

---

- A data type is called simple if variables of that type can store only one value at a time
- A structured data type is one in which each data item is a collection of other data items

# Arrays

- Array: a collection of a fixed number of components wherein all of the components have the same data type
- In a one-dimensional array, the components are arranged in a list form
- Syntax for declaring a one-dimensional array:

```
dataType arrayName[intExp];
```

`intExp` evaluates to a positive integer

# Arrays (continued)

- Example:

```
int num[5];
```

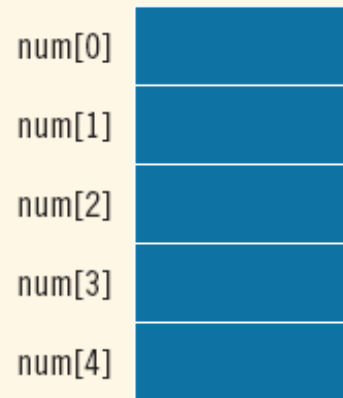

FIGURE 9-1 Array num

# Accessing Array Components

- General syntax:

```
arrayName[indexExp]
```

where `indexExp`, called an **index**, is any expression whose value is a nonnegative integer

- Index value specifies the position of the component in the array
- `[]` is the **array subscripting operator**
- The array index always starts at 0

# Accessing Array Components (continued)

```
int list[10];
```

FIGURE 9-2 Array list

# Accessing Array Components (continued)

```
list[5] = 34;
```

**FIGURE 9-3** Array `list` after execution of the statement `list[5]= 34;`

# Accessing Array Components (continued)

```
list[3] = 10;  
list[6] = 35;  
list[5] = list[3] + list[6];
```

**FIGURE 9-4** Array `list` after execution of the statements `list[3]= 10;`, `list[6]= 35;`, and `list[5] = list[3] + list[6];`

# Accessing Array Components (continued)

## EXAMPLE 9-2

You can also declare arrays as follows:

```
const int ARRAY_SIZE = 10;  
int list[ARRAY_SIZE];
```

That is, you can first declare a named constant and then use the value of the named constant to declare an array and specify its size.

### NOTE

When you declare an array, its size must be known. For example, you cannot do the following:

```
int arraySize; //Line 1  
  
cout << "Enter the size of the array: "; //Line 2  
cin >> arraySize; //Line 3  
cout << endl; //Line 4  
  
int list[arraySize]; //Line 5; not allowed
```

# Processing One-Dimensional Arrays

---

- Some basic operations performed on a one-dimensional array are:
  - Initializing
  - Inputting data
  - Outputting data stored in an array
  - Finding the largest and/or smallest element
- Each operation requires ability to step through the elements of the array
- Easily accomplished by a loop

# Processing One-Dimensional Arrays (continued)

- Consider the declaration

```
int list[100]; //array of size 100
int i;
```

- Using `for` loops to access array elements:

```
for (i = 0; i < 100; i++) //Line 1
    //process list[i]     //Line 2
```

- Example:

```
for (i = 0; i < 100; i++) //Line 1
    cin >> list[i];      //Line 2
```

## EXAMPLE 9-3

```
double sales[10];
int index;
double largestSale, sum, average;
```

### Initializing an array:

```
for (index = 0; index < 10; index++)
    sales[index] = 0.0;
```

### Reading data into an array:

```
for (index = 0; index < 10; index++)
    cin >> sales[index];
```

### Printing an array:

```
for (index = 0; index < 10; index++)
    cout << sales[index] << " ";
```

### Finding the sum and average of an array:

```
sum = 0;
for (index = 0; index < 10; index++)
    sum = sum + sales[index];
```

```
average = sum / 10;
```

### Largest element in the array:

```
maxIndex = 0;
for (index = 1; index < 10; index++)
    if (sales[maxIndex] < sales[index])
        maxIndex = index;
largestSale = sales[maxIndex];
```

# Array Index Out of Bounds

- If we have the statements:

```
double num[10];  
int i;
```

- The component `num[i]` is valid if  $i = 0, 1, 2, 3, 4, 5, 6, 7, 8, \text{ or } 9$
- The index of an array is in bounds if the `index`  $\geq 0$  and the `index`  $\leq \text{ARRAY\_SIZE}-1$ 
  - Otherwise, we say the `index` is out of bounds
- In C++, there is no guard against indices that are out of bounds

# Array Initialization During Declaration

- Arrays can be initialized during declaration
  - In this case, it is not necessary to specify the size of the array
    - Size determined by the number of initial values in the braces

- Example:

```
double sales[] = {12.25, 32.50, 16.90, 23, 45.68};
```

# Partial Initialization of Arrays During Declaration

- The statement:

```
int list[10] = {0};
```

declares `list` to be an array of 10 components and initializes all of them to zero

- The statement:

```
int list[10] = {8, 5, 12};
```

declares `list` to be an array of 10 components, initializes `list[0]` to 8, `list[1]` to 5, `list[2]` to 12 and all other components are initialized to 0

# Partial Initialization of Arrays During Declaration (continued)

- The statement:

```
int list[] = {5, 6, 3};
```

declares `list` to be an array of 3 components and initializes `list[0]` to 5, `list[1]` to 6, and `list[2]` to 3

- The statement:

```
int list[25] = {4, 7};
```

declares an array of 25 components; initializes `list[0]` to 4 and `list[1]` to 7; all other components are initialized to 0

# Some Restrictions on Array Processing

- Consider the following statements:

```
int myList[5] = {0, 4, 8, 12, 16}; //Line 1
int yourList[5]; //Line 2
```

- C++ does not allow aggregate operations on an array:

```
yourList = myList; //illegal
```

- Solution:

```
for (int index = 0; index < 5; index ++)  
    yourList[index] = myList[index];
```

# Some Restrictions on Array Processing (continued)

- The following is illegal too:

```
cin >> yourList; //illegal
```

- Solution:

```
for (int index = 0; index < 5; index ++)  
    cin >> yourList[index];
```

- The following statements are legal, but do not give the desired results:

```
cout << yourList;
```

```
if (myList <= yourList)
```

```
·  
·
```

# Arrays as Parameters to Functions

- Arrays are passed by reference only
- The symbol `&` is *not* used when declaring an array as a formal parameter
- The size of the array is usually omitted
  - If provided, it is ignored by the compiler

## EXAMPLE 9-5

Consider the following function:

```
void funcArrayAsParam(int listOne[], double listTwo[])
{
    .
    .
    .
}
```

# Constant Arrays as Formal Parameters

## EXAMPLE 9-6

```
//Function to initialize an int array to 0.
//The array to be initialized and its size are passed
//as parameters. The parameter listSize specifies the
//number of elements to be initialized.
void initializeArray(int list[], int listSize)
{
    int index;

    for (index = 0; index < listSize; index++)
        list[index] = 0;
}

//Function to print the elements of an int array.
//The array to be printed and the number of elements
//are passed as parameters. The parameter listSize
//specifies the number of elements to be printed.
void printArray(const int list[], int listSize)
{
    int index;

    for (index = 0; index < listSize; index++)
        cout << list[index] << " ";
}
```

# Base Address of an Array and Array in Computer Memory

- The base address of an array is the address, or memory location of the first array component
- If `list` is a one-dimensional array, its base address is the address of `list[0]`
- When we pass an array as a parameter, the base address of the actual array is passed to the formal parameter

**FIGURE 9-6** Array `myList` and the addresses of its components

# Functions Cannot Return a Value of the Type Array

---

- C++ does not allow functions to return a value of the type array

# Integral Data Type and Array Indices

- C++ allows any integral type to be used as an array index
- Example:

```
enum paintType {GREEN, RED, BLUE, BROWN, WHITE, ORANGE, YELLOW};  
double paintSale[7];  
paintType paint;  
  
for (paint = GREEN; paint <= YELLOW;  
     paint = static_cast<paintType>(paint + 1))  
    paintSale[paint] = 0.0;  
  
paintSale[RED] = paintSale[RED] + 75.69;
```

# Other Ways to Declare Arrays

```
const int NO_OF_STUDENTS = 20;  
int testScores[NO_OF_STUDENTS];  
  
const int SIZE = 50;           //Line 1  
typedef double list[SIZE];    //Line 2  
  
list yourList;                //Line 3  
list myList;                  //Line 4
```

# C-Strings (Character Arrays)

- Character array: an array whose components are of type `char`
- C-strings are null-terminated (`'\0'`) character arrays
- Example:
  - `'A'` is the character `A`
  - `"A"` is the C-string `A`
    - `"A"` represents two characters, `'A'` and `'\0'`

# C-Strings (Character Arrays) (continued)

---

- Consider the statement

```
char name[16];
```

- Since C-strings are null terminated and `name` has 16 components, the largest string that it can store has 15 characters
- If you store a string of length, say 10 in `name`
  - The first 11 components of `name` are used and the last five are left unused

# C-Strings (Character Arrays) (continued)

---

- The statement

```
char name[16] = "John";
```

declares an array `name` of length 16 and stores the C-string "John" in it

- The statement

```
char name[] = "John";
```

declares an array `name` of length 5 and stores the C-string "John" in it

# C-Strings (Character Arrays) (continued)

TABLE 9-1 `strcpy`, `strcmp`, and `strlen` functions

Function	Effect
<code>strcpy(s1, s2)</code>	Copies the string <code>s2</code> into the string variable <code>s1</code> The length of <code>s1</code> should be at least as large as <code>s2</code>
<code>strcmp(s1, s2)</code>	Returns a value $< 0$ if <code>s1</code> is less than <code>s2</code> Returns 0 if <code>s1</code> and <code>s2</code> are the same Returns a value $> 0$ if <code>s1</code> is greater than <code>s2</code>
<code>strlen(s)</code>	Returns the length of the string <code>s</code> , excluding the null character

# String Comparison

- C-strings are compared character by character using the collating sequence of the system
- If we are using the ASCII character set
  - "Air" < "Boat"
  - "Air" < "An"
  - "Bill" < "Billy"
  - "Hello" < "hello"

## EXAMPLE 9-8

Suppose you have the following statements:

```
char studentName[21];  
char myname[16];  
char yourname[16];
```

The following statements show how string functions work:

Statement	Effect
<pre>strcpy(myname, "John Robinson");</pre>	<pre>Myname = "John Robinson"</pre>
<pre>strlen("John Robinson");</pre>	Returns 13, the length of the string "John Robinson"
<pre>int len; len = strlen("Sunny Day");</pre>	Stores 9 into len
<pre>strcpy(yourname, "Lisa Miller"); strcpy(studentName, yourname);</pre>	<pre>yourname = "Lisa Miller" studentName = "Lisa Miller"</pre>
<pre>strcmp("Bill", "Lisa");</pre>	Returns a value < 0
<pre>strcpy(yourname, "Kathy Brown"); strcpy(myname, "Mark G. Clark"); strcmp(myname, yourname);</pre>	<pre>yourname = "Kathy Brown" myname = "Mark G. Clark" Returns a value &gt; 0</pre>

# Reading and Writing Strings

---

- Most rules that apply to arrays apply to C-strings as well
- Aggregate operations, such as assignment and comparison, are not allowed on arrays
- Even the input/output of arrays is done component-wise
- The one place where C++ allows aggregate operations on arrays is the input and output of C-strings (that is, character arrays)

# String Input

- `cin >> name;` stores the next input C-string into `name`
- To read strings with blanks, use `get`:

```
cin.get(str, m+1);
```

- Stores the next `m` characters into `str` but the newline character is not stored in `str`
- If the input string has fewer than `m` characters, the reading stops at the newline character

# String Output

- `cout << name;` outputs the content of `name` on the screen
  - `<<` continues to write the contents of `name` until it finds the null character
  - If `name` does not contain the null character, then we will see strange output
    - `<<` continues to output data from memory adjacent to `name` until `'\0'` is found

# Specifying Input/Output Files at Execution Time

- You can let the user specify the name of the input and/or output file at execution time:

```
ifstream infile;
ofstream outfile;

char fileName[51];    //assume that the file name is at most
                    //50 characters long

cout << "Enter the input file name: ";
cin >> fileName;

infile.open(fileName); //open the input file
.
.
.

cout << "Enter the output file name: ";
cin >> fileName;

outfile.open(fileName); //open the output file
```

# string Type and Input/Output Files

- Argument to the function `open` must be a null-terminated string (a C-string)
- If we use a variable of type `string` to read the name of an I/O file, the value must first be converted to a C-string before calling `open`
- Syntax:

```
strVar.c_str()
```

where `strVar` is a variable of type `string`

# Parallel Arrays

- Two (or more) arrays are called parallel if their corresponding components hold related information
- Example:

```
int studentId[50];  
char courseGrade[50];
```

23456	A
86723	B
22356	C
92733	B
11892	D
.	
.	
.	

# Two-Dimensional Arrays

- Two-dimensional array: collection of a fixed number of components (of the same type) arranged in two dimensions
  - Sometimes called matrices or tables
- Declaration syntax:

```
dataType  arrayName[intExp1][intExp2];
```

where `intexp1` and `intexp2` are expressions yielding positive integer values, and specify the number of rows and the number of columns, respectively, in the array

# Two-Dimensional Arrays (continued)

```
double sales[10][5];
```

sales	[0]	[1]	[2]	[3]	[4]
[0]					
[1]					
[2]					
[3]					
[4]					
[5]					
[6]					
[7]					
[8]					
[9]					

FIGURE 9-8 Two-dimensional array `sales`

# Accessing Array Components

- Syntax:

```
arrayName[indexExp1][indexExp2]
```

where `indexexp1` and `indexexp2` are expressions yielding nonnegative integer values, and specify the row and column position

# Accessing Array Components (continued)

```
sales[5][3] = 25.75;
```

sales	[0]	[1]	[2]	[3]	[4]
[0]					
[1]					
[2]					
[3]					
[4]					
[5]				25.75	
[6]					
[7]					
[8]					
[9]					

sales [5] [3]

FIGURE 9-9 sales[5][3]

# Two-Dimensional Array Initialization During Declaration

- Two-dimensional arrays can be initialized when they are declared:

```
int board[4][3] = {{2, 3, 1},  
                  {15, 25, 13},  
                  {20, 4, 7},  
                  {11, 18, 14}};
```

- Elements of each row are enclosed within braces and separated by commas
- All rows are enclosed within braces
- For number arrays, if all components of a row aren't specified, unspecified ones are set to 0

# Two-Dimensional Arrays and Enumeration Types

```
enum carType {GM, FORD, TOYOTA, BMW, NISSAN, VOLVO};  
enum colorType {RED, BROWN, BLACK, WHITE, GRAY};  
  
int inStock[NUMBER_OF_ROWS][NUMBER_OF_COLUMNS];  
inStock[FORD][WHITE] = 15;
```

inStock	[RED]	[BROWN]	[BLACK]	[WHITE]	[GRAY]
[GM]					
[FORD]				15	
[TOYOTA]					
[BMW]					
[NISSAN]					
[VOLVO]					

FIGURE 9-12 `inStock[FORD][WHITE]`

# Processing Two-Dimensional Arrays

- Ways to process a two-dimensional array:
  - Process the entire array
  - Process a particular row of the array, called row processing
  - Process a particular column of the array, called column processing
- Each row and each column of a two-dimensional array is a one-dimensional array
  - To process, use algorithms similar to processing one-dimensional arrays

# Processing Two-Dimensional Arrays (continued)

```
const int NUMBER_OF_ROWS = 7;    //This can be set to any number.
const int NUMBER_OF_COLUMNS = 6; //This can be set to any number.

int matrix[NUMBER_OF_ROWS][NUMBER_OF_COLUMNS];
int row;
int col;
int sum;
int largest;
int temp;
```

matrix	[0]	[1]	[2]	[3]	[4]	[5]
[0]						
[1]						
[2]						
[3]						
[4]						
[5]						
[6]						

FIGURE 9-13 Two-dimensional array `matrix`

# Initialization

- To initialize row number 4 (i.e., fifth row) to 0

```
row = 4;
for (col = 0; col < NUMBER_OF_COLUMNS; col++)
    matrix[row][col] = 0;
```

- To initialize the entire matrix to 0:

```
for (row = 0; row < NUMBER_OF_ROWS; row++)
    for (col = 0; col < NUMBER_OF_COLUMNS; col++)
        matrix[row][col] = 0;
```

# Print

- To output the components of `matrix`:

```
for (row = 0; row < NUMBER_OF_ROWS; row++)
{
    for (col = 0; col < NUMBER_OF_COLUMNS; col++)
        cout << setw(5) << matrix[row][col] << " ";

    cout << endl;
}
```

# Input

- To input data into each component of matrix:

```
for (row = 0; row < NUMBER_OF_ROWS; row++)  
    for (col = 0; col < NUMBER_OF_COLUMNS; col++)  
        cin >> matrix[row][col];
```

# Sum by Row

- To find the sum of row number 4 of `matrix`:

```
sum = 0;
row = 4;
for (col = 0; col < NUMBER_OF_COLUMNS; col++)
    sum = sum + matrix[row][col];
```

- To find the sum of each individual row:

```
//Sum of each individual row
for (row = 0; row < NUMBER_OF_ROWS; row++)
{
    sum = 0;
    for (col = 0; col < NUMBER_OF_COLUMNS; col++)
        sum = sum + matrix[row][col];

    cout << "Sum of row " << row + 1 << " = " << sum << endl;
}
```

# Sum by Column

- To find the sum of each individual column:

```
//Sum of each individual column
for (col = 0; col < NUMBER_OF_COLUMNS; col++)
{
    sum = 0;
    for (row = 0; row < NUMBER_OF_ROWS; row++)
        sum = sum + matrix[row][col];

    cout << "Sum of column " << col + 1 << " = " << sum
        << endl;
}
```

# Largest Element in Each Row and Each Column

```
//Largest element in each row
for (row = 0; row < NUMBER_OF_ROWS; row++)
{
    largest = matrix[row][0]; //Assume that the first element
                             //of the row is the largest.
    for (col = 1; col < NUMBER_OF_COLUMNS; col++)
        if (largest < matrix[row][col])
            largest = matrix[row][col];

    cout << "The largest element in row " << row + 1 << " = "
         << largest << endl;
}

//Largest element in each column
for (col = 0; col < NUMBER_OF_COLUMNS; col++)
{
    largest = matrix[0][col]; //Assume that the first element
                              //of the column is the largest.
    for (row = 1; row < NUMBER_OF_ROWS; row++)
        if (largest < matrix[row][col])
            largest = matrix[row][col];

    cout << "The largest element in column " << col + 1
         << " = " << largest << endl;
}
```

# Reversing Diagonal

- Before:

matrix	[0]	[1]	[2]	[3]
[0]	1	8	10	11
[1]	34	2	12	45
[2]	0	13	3	20
[3]	14	35	56	4

FIGURE 9-14 Two-dimensional array `matrix`

# Reversing Diagonal (continued)

- To reverse both the diagonals:

```
    //Reverse the main diagonal
for (row = 0; row < NUMBER_OF_ROWS / 2; row++)
{
    temp = matrix[row][row];
    matrix[row][row] =
        matrix[NUMBER_OF_ROWS - 1 - row][NUMBER_OF_ROWS - 1 - row];
    matrix[NUMBER_OF_ROWS - 1 - row][NUMBER_OF_ROWS - 1 - row]
        = temp;
}
```

```
    //Reverse the opposite diagonal
for (row = 0; row < NUMBER_OF_ROWS / 2; row++)
{
    temp = matrix[row][NUMBER_OF_ROWS - 1 - row];
    matrix[row][NUMBER_OF_ROWS - 1 - row] =
        matrix[NUMBER_OF_ROWS - 1 - row][row];
    matrix[NUMBER_OF_ROWS - 1 - row][row] = temp;
}
```

# Reversing Diagonal (continued)

- After:

matrix	[0]	[1]	[2]	[3]
[0]	4	8	10	14
[1]	34	3	13	45
[2]	0	12	2	20
[3]	11	35	56	1

FIGURE 9-15 The array `matrix` after reversing diagonals

# Passing Two-Dimensional Arrays as Parameters to Functions

---

- Two-dimensional arrays can be passed as parameters to a function
  - Pass by reference
    - Base address (address of first component of the actual parameter) is passed to formal parameter
- Two-dimensional arrays are stored in row order
- When declaring a two-dimensional array as a formal parameter, can omit size of first dimension, but not the second

# Arrays of Strings

---

- Strings in C++ can be manipulated using either the data type `string` or character arrays (C-strings)
- On some compilers, the data type `string` may not be available in Standard C++ (i.e., non-ANSI/ISO Standard C++)

# Arrays of Strings and the `string` Type

- To declare an array of 100 components of type `string`:  

```
string list[100];
```
- Basic operations, such as assignment, comparison, and input/output, can be performed on values of the `string` type
- The data in `list` can be processed just like any one-dimensional array

# Arrays of Strings and C-Strings (Character Arrays)

```
char list[100][16];  
strcpy(list[1], "Snow White");
```

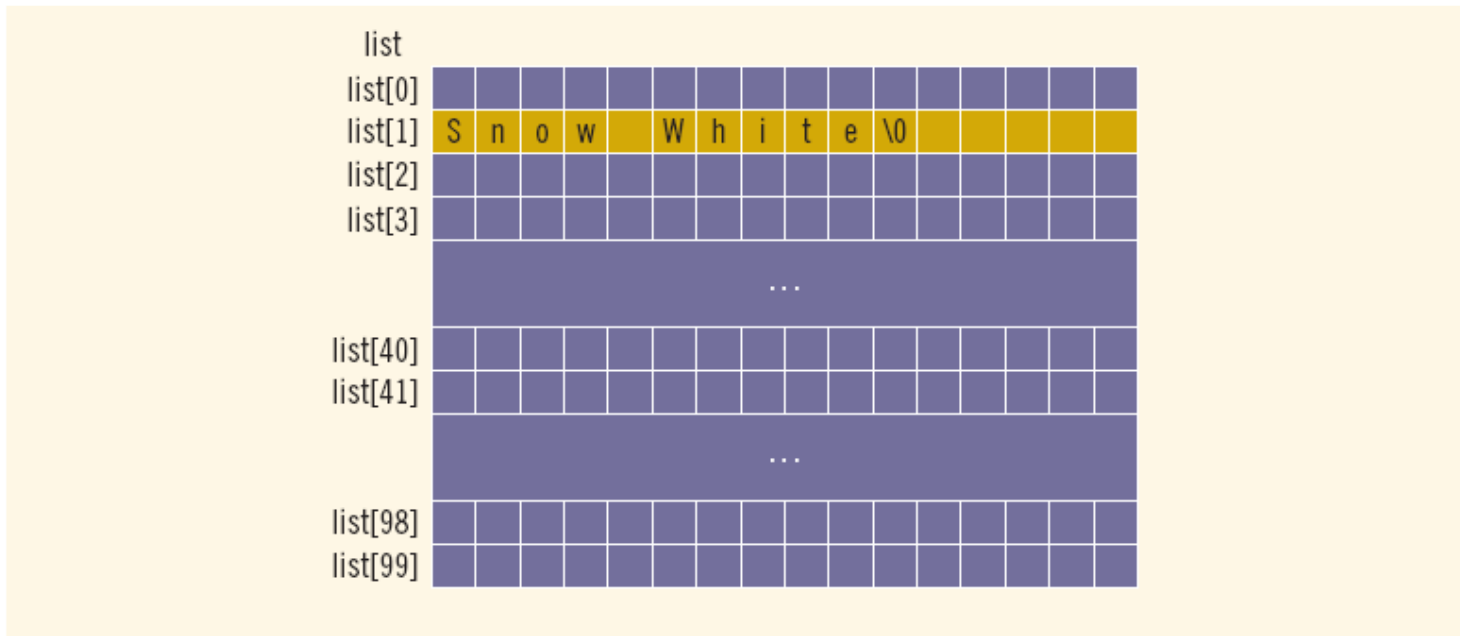

FIGURE 9-17 Array list, showing list[1]

```
for (j = 0; j < 100; j++)  
    cin.get(list[j], 16);
```

# Another Way to Declare a Two-Dimensional Array

- Consider the following:

```
const int NUMBER_OF_ROWS = 20;  
const int NUMBER_OF_COLUMNS = 10;
```

```
typedef int tableType[NUMBER_OF_ROWS][NUMBER_OF_COLUMNS];
```

- To declare an array of 20 rows and 10 columns:

```
tableType matrix;
```

# Multidimensional Arrays

- Multidimensional array: collection of a fixed number of elements (called components) arranged in  $n$  dimensions ( $n \geq 1$ )
  - Also called an  $n$ -dimensional array
- Declaration syntax:

```
dataType arrayName[intExp1][intExp2] ... [intExpn];
```

- To access a component:

```
arrayName[indexExp1][indexExp2] ... [indexExpn]
```

# Multidimensional Arrays (continued)

---

- When declaring a multidimensional array as a formal parameter in a function
  - Can omit size of first dimension but not other dimensions
- As parameters, multidimensional arrays are passed by reference only
- A function cannot return a value of the type array
- There is no check if the array indices are within bounds

# Programming Example: Code Detection

---

- When a message is transmitted in secret code over a transmission channel, it is usually transmitted as a sequence of bits (0s and 1s)
- Due to noise in the transmission channel, the transmitted message may become corrupted
  - Message received at destination is not the same as the message transmitted
  - Some of the bits may have been changed

# Programming Example: Code Detection (continued)

---

- Several techniques to check the validity of the transmitted message at the destination
- One technique is to transmit the same message twice
  - At the destination, both copies of the message are compared bit by bit
  - If the corresponding bits are the same, the message received is error-free

# Programming Example: Code Detection (continued)

---

- We write a program to check if the message received at the destination is error-free
- For simplicity, assume that:
  - The secret code representing the message is a sequence of digits (0 to 9)
  - The maximum length of the message is 250 digits
- The first number in the message is the length of the message

# Programming Example: Code Detection (continued)

- If the secret code is

7 9 2 7 8 3 5 6

then the message is seven digits long

- The above message is transmitted (twice) as

7 9 2 7 8 3 5 6 7 9 2 7 8 3 5 6

- Input: a file containing the secret code and its copy
- Output: the secret code, its copy, and a message if the received code is error-free

# Programming Example: Code Detection (continued)

- The results are output in the following form:

Code	Digit	Code	Digit	Copy
	9		9	
	2		2	
	7		7	
	8		8	
	3		3	
	5		5	
	6		6	

- Message transmitted OK

# Programming Example: Problem Analysis

---

- Because we have to compare digits of the secret code and its copy:
  - First, read the secret code and store it in an array
  - Next, read first digit of the copy and compare it with the first digit of the code, and so on
  - If any corresponding digits are not the same, print a message next to the digits
- The first number in the secret code, and in the copy, indicates the length of the code

# Programming Example: Algorithm Design

---

- Open the input and output files
- If the input file does not exist, exit the program
- Read the length of the secret code
- If the length of the secret code is greater than 250, terminate the program because the maximum length of the code in this program is 250
- Read and store the secret code into an array

# Programming Example: Algorithm Design (continued)

- Read the length of the copy
- If the length of the secret code and its copy are the same, compare the codes; otherwise, print an error message
- Note: To simplify function `main`, write a function, `readCode`, to read the secret code and another function, `compareCode`, to compare the codes

# Programming Example:

## `readCode`

- First, read length of secret code
- If length of secret code is greater than 250
  - Set `lenCodeOk` (a reference parameter) to `false` and the function terminates
- Value of `lenCodeOk` is passed to calling function to indicate if secret code was read successfully
- If length of code is less than 250, `readCode` reads and stores secret code into an array

# Programming Example: readCode (continued)

```
void readCode(ifstream& infile, int list[], int& length,
              bool& lenCodeOk)
{
    int count;

    lenCodeOk = true;

    infile >> length; //get the length of the secret code

    if (length > MAX_CODE_SIZE)
    {
        lenCodeOk = false;
        return;
    }

    //Get the secret code.
    for (count = 0; count < length; count++)
        infile >> list[count];
}
```

# Programming Example:

## `compareCode`

---

- Set a `bool` variable `codeOk` to true
- If length of code and copy are not equal
  - Output error message and terminate function
- For each digit in input file
  - Read the next digit of secret code copy
  - Output digits from code and copy
  - If corresponding digits are not equal, output error message and set `codeOk` to `false`
- If `codeOk`, output message indicating code transmitted OK, else output an error message

# Programming Example: compareCode (continued)

```
void compareCode(ifstream& infile, ofstream& outfile,
                int list[], int length)
{
    //Step a
    int length2;
    int digit;
    bool codeOk;
    int count;

    codeOk = true; //Step b

    infile >> length2; //Step c

    if (length != length2) //Step d
    {
        cout << "The original code and its copy "
              << "are not of the same length."
              << endl;
        return;
    }

    outfile << "Code Digit    Code Digit Copy"
            << endl;
```

# Programming Example: compareCode (continued)

```
for (count = 0; count < length; count++)           //Step e
{
    infile >> digit;                               //Step e.1
    outfile << setw(5) << list[count]
           << setw(17) << digit;                   //Step e.2

    if (digit != list[count])                       //Step e.3
    {
        outfile << " code digits are not the same"
                << endl;
        codeOk = false;
    }
    else
        outfile << endl;
}

if (codeOk)                                        //Step f
    outfile << "Message transmitted OK."
           << endl;
else
    outfile << "Error in transmission. "
           << "Retransmit!!" << endl;
}
```

# Programming Example: Main Algorithm

---

- Declare variables
- Open the files
- Call `readCode` to read the secret code
- If (length of the secret code  $\leq$  250)
  - Call `compareCode` to compare the codes
- else
  - Output an appropriate error message

# Summary

---

- Array: structured data type with a fixed number of components of the same type
  - Components are accessed using their relative positions in the array
- Elements of a one-dimensional array are arranged in the form of a list
- An array index can be any expression that evaluates to a nonnegative integer
  - Must always be less than the size of the array

# Summary (continued)

---

- The base address of an array is the address of the first array component
- When passing an array as an actual parameter, you use only its name
  - Passed by reference only
- A function cannot return a value of the type array
- In C++, C-strings are null terminated and are stored in character arrays

# Summary (continued)

---

- Commonly used C-string manipulation functions include:
  - `strcpy`, `strcmp`, and `strlen`
- Parallel arrays are used to hold related information
- In a two-dimensional array, the elements are arranged in a table form

# Summary

---

- To access an element of a two-dimensional array, you need a pair of indices:
  - One for the row position
  - One for the column position
- In row processing, a two-dimensional array is processed one row at a time
- In column processing, a two-dimensional array is processed one column at a time
